

# GNU Radio History: Example

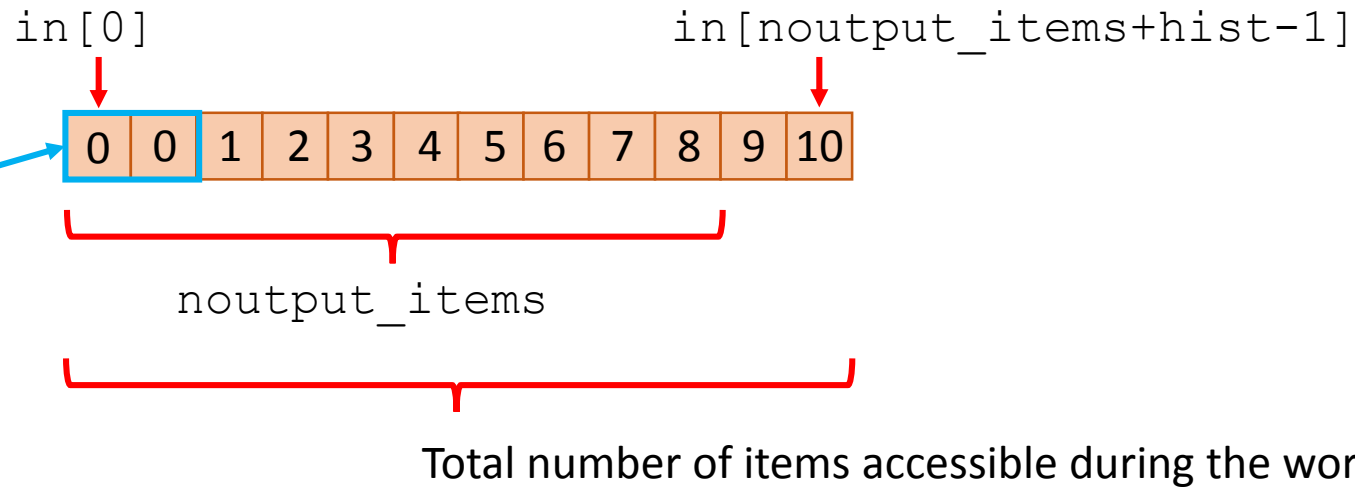

Let's say that `history()` is 3. The block reads in the following items from the upstream buffer:

The scheduler allows the data input buffer to be processed piecewise in a series of calls to the work function. Let's say the first 3 work calls give `noutput_items` values of 10, 8 and 10, respectively.

## 1<sup>st</sup> work call

`noutput_items = 10`

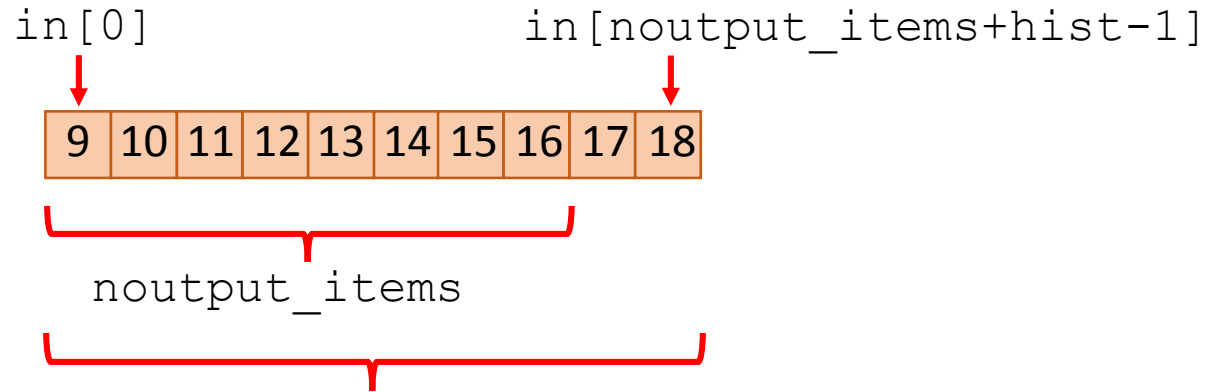

setting `history > 1` prepends `history() - 1` zeros to the available items in the first work call

# GNU Radio History: Example

## 2<sup>nd</sup> work call

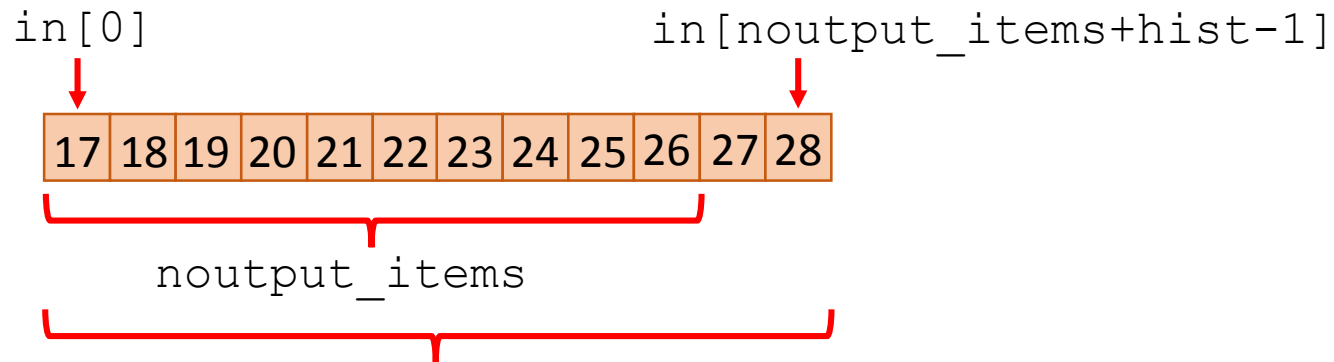

`noutput_items = 8`

Total number of items accessible during the work call

## 3<sup>rd</sup> work call

`noutput_items = 10`

Total number of items accessible during the work call

# Summary

Setting history to  $n$  increases the number of items available to the work function in any given work call by  $n-1$ . This is done by giving  $n-1$  zero-value items at the beginning of the first work call.

History of length  $n$  means:

- The  $n-1$  items *beyond* `noutput_items` can be processed in the work call
- Block latency of  $n-1$  of items
- Tags can be set in the first `noutput_items` giving the appearance of tagging backward in time
